demonstrating that mammalian growth hormone and other metabolic pathways affect human life. There are two main potential mechanisms for this and these potential processes play an important role (in particular) in health and longevity. These findings appear to reflect an evolutionary point of view but are not evidence of change in biological functions. Furthermore, there appears uncertainty about whether this could include a significant difference in the level of human metabolism, whether it contributes to or is directly influenced by increased human energy expenditure [7]. Overall, this study suggests that the biological substrates associated with health change, changes in genetic differentiation, and adaptation to health situations are not just genetically related. Instead we suggest that adaptive immunity, physiological changes in the inmune system, hormone and metabolic pathways, and even, perhaps even, the formation of longevity, epigenetic properties, alterations in the hormonal system, or changes in environmental factors including genetic information storage and the development of complex disease markers.
